Abstract: The radiation hazards indices of common silhouette plants used in homes decoration were studied at two seasons; spring and summer. Twelve species of silhouette plants were collected from nurseries in Baghdad, six of them were collected in spring season others in summer season, each group were positioned in the laboratory at normal conditions. The measurements were carried out using NaI (Tl) gamma-ray spectrometry. Results shown a little difference between the mean specific activities of the radionuclides, they were 161.2±11.8, 11.2±1.2Bq/kg, and 5.8±0.5Bq/kg in spring season plants, 159.5±21.1, 5.4±0.8Bq/kg, and 6.4±0.4 in summer season plants for K-40, Bi-214, and Tl-208 respectively. According to these results the mean radiation hazard indices (The radium equivalent activity, absorbed dose rate, annual effective dose equivalent, external hazard indices, annual gonadal dose and excess lifetime cancer risk) were also convergent to each other in plant samples of both groups. The highest specific activities were appeared in Dareseny plant 197.11Bq/kg, 15.94Bq/kg, and 7.8 Bq/kg for K-40, Bi-214, and Tl-208 respectively. While in summer season the K-40 (265.9Bq/Kg) and Bi-214 (8.6Bq/Kg) were higher in sygonium, and Tl-208 is higher in Ficus Elatic (9.2Bq/Kg). All results are within the recommended values.

Keywords: Hazard Indices, Nai (Tl) Detector, Silhouette Plants, Specific Activity, Radium Equivalent Activity

1. Introduction

Human beings are exposed to background radiation that stems both from natural and man-made sources [1, 2]. Natural background radiation, which is equivalent to 2.4mSv per person, Radon occurs widely in the environment, especially in rocks, soil, building materials and water [3, 4]. Primordial radionuclides of the decay series U-238 and Th-232 exist naturally in the earth's crust [5]. These radionuclides enter the soil through the weathering of the earth crust [6]. Concentrations of U-238 and Th-232 in soil (one of the main factors affecting plant uptake of the radionuclides) differ significantly depending on the soil type, parent rocks, climate, relief, vegetation season and many other factors [7, 8]. These radioactive elements find their way into plants by direct contact with atmosphere containing radionuclide, or by absorption of soluble radionuclide from soil-water to root uptake and re-suspended of radionuclide from soil. The radionuclide deposited directly with plant is either by dry deposition such as wind or by wet deposition such as rain. Meanwhile, the availability of radionuclide in soil and the uptake potential of each radioactive element are the main factors controlling the rate of uptake radionuclide from soil to plant [9, 10].

Plants acquire these radionuclides via their roots or leaves, and animals acquire them through consumption of plants, phosphate-based mineral food supplements and soils [11, 12]. Doses from radionuclides of natural origin in terrestrial foodstuffs are currently much higher than those from artificial radionuclides [13]. Radionuclide uptake of plants depends upon different factors such as soil type, texture, pH, conductivity, and carbonate and sulphite contents [14]. The entry of trace contaminants, which are present in the terrestrial environment, into human food chains is controlled in the long term by their uptake by plant roots [15]. It was
found that the tobacco plant contains leaves with leaves to help increase the adsorption of radon, tobacco leaves; it contains Sticky hair like structures on both sides of tobacco leave [16].

The aim of this study is to determine the activity concentration, and radiological risk of radionuclide Ra-226, -232 and K-40 in different silhouette plant samples.

2. Materials and Methods

2.1. Samples Collection

Two groups of different species of silhouette plants are collected from various nurseries located in Baghdad. Each group is consists of six samples; first group includes plant samples collected in spring season at 8/5/2018 as in figure 1, other group consists of plants collected in summer season at 24/6/2018 as in figure 2. Both groups were placed in the laboratory for 30 days in order to subject to the same natural laboratory conditions. The samples prepared by cutting, dried with oven at 80°C for 2h, crushed to fine powder, sieved through 630µm sieve to be homogenizes in size, stored in sealed in Marnille beaker, and left for four weeks to reach the secular equilibrium before they examined by the spectroscopy.

![Figure 1. The silhouette Plants collected in spring season.](image1)

![Figure 2. The silhouette Plants collected in summer season.](image2)

2.2. NaI (Tl) Spectroscopy

A scintillation detector NaI (Tl) gamma spectroscopy of crystal dimension of 3”× 3”shielded with lead, SCIOIX model 51851, Germany origin have been used to perform this study. The system has a digital multichannel analyzer (bright multichannel SPEC model bMCA) of 4096 channels and 695V operation voltage. The time of examination used were 24hr (86400 s) [17, 18].

2.3. Specific Activity Calculations

The activity concentrations of the plant measured by gamma spectrometry were calculated using the following relation [19, 20]:

\[
A(t) = \frac{N}{\varepsilon (E_γ) \times t \times (m \times t) \times 100}
\]

(1)

Where N is the net peak area under the specific peak, t is the time of measurement in second, I (E_γ) is the abundance of energy, ε (E_γ) is the detection efficiency at energy E_γ, and m is the mass of the measured sample in kg.

2.4. Radiological Hazards Assessment

2.4.1. Radium Equivalent Activity

Radium equivalent activity (Ra_{eq}) is used to ensure the uniformity in the distribution of natural radionuclides ^{226}Ra, ^{232}Th, and ^{40}K and is given by [21, 22]:

\[
Ra_{eq} \text{ (Bq/kg)} = A_{Ra} + 1.43A_{Th} + 0.077A_{K}
\]

(2)

Where A_{Ra}, A_{Th}, and A_{K} are the specific activities of ^{226}Ra, ^{232}Th, and ^{40}K respectively.

2.4.2. External Hazard Index (Hex), Gamma Index (I_γ) and Alpha Index (I_α)

External hazard Index is reflecting the external radiation that the samples were exposed, it's defined by [23, 24] as:

\[
Hex = \frac{A_{Ra}}{370} + \frac{A_{Th}}{259} + \frac{A_{K}}{4810} \leq 1
\]

(3)

The gamma index and Alpha index was calculated by using the following equation [25, 26]:

\[
I_γ = \frac{A_{Ra}}{300} + \frac{A_{Th}}{200} + \frac{A_{K}}{3000} \leq 1
\]

(4)

\[
I_α = A_{Ra}/200 \leq 1
\]

(5)

2.4.3. Absorbed Dose Rate (D_γ), Annual Effective Dose Equivalent (AEDE)

The absorbed dose rate in air due to gamma radiations in outdoor air at 1 m above the ground surface was calculated as follow [27]:

\[
D_γ \text{ (nGy/h)} = 0.462A_{Ra} + 0.621A_{Th} + 0.0417A_{K}
\]

(6)

The annual effective dose rate was calculated by the following equation [28]:

\[
AEDE_\text{in (mSv/y)} = D_γ \times 10^6 \times 8760 \text{ h/y} \times 0.80 \times 0.7 \text{ Sv/Gy}
\]

(7)

2.4.4. Annual Gonadal Dose Equivalent (AGDE)

The annual gonadal dose equivalent applied on endocrine according to the concentrations of ^{226}Ra, ^{232}Th, and ^{40}K was...
calculated by [29]:

$$\text{AGDE (mSv.y}^{-1}) = (3.09\times \text{ARa} + 4.18\times \text{ATh} + 0.314\times \text{AK}) \times 10^{-3}$$  \hspace{1cm} (8)

### 2.4.5. Excess lifetime Cancer Risk (ELCR) of Human

The Excess lifetime cancer risk (ELCR) was calculated by:

$$\text{ELCR} = \text{AEDE} \times \text{DL} \times \text{RF}$$  \hspace{1cm} (9)

Where, \(\text{AEDE}\) is the annual effective dose equivalent, \(\text{DL}\) is the average life duration (estimated to be 70 years), and \(\text{RF}\) is the risk factor 0.05 Sv\(^{-1}\) [30].

## 3. Results and Discussion

The mean specific activates of the radionuclides\(^{226}\)Ra, \(^{232}\)Th, and \(^{40}\)K that have been detected in the two group are shown in table 1.

### Table 1. Specific activity concentrations of silhouette plants.

Note: W. A. = Worldwide Average

It is observed that the mean specific activates of first group of plants samples collected in spring season are higher than the mean values of the second group of plants samples collected in summer season. As they were 161.2±11.8Bq/kg, and 11.2±2.3Bq/kg at first group, and 159.5±21.1Bq/kg, and 5.4±0.8Bq/kg at second group for \(^{40}\)K and \(^{214}\)Bi respectively. Except for Tl-208 at which mean specific activates of first group 5.8±5Bq/kg was lower than the mean specific activates of the second group 6.4±0.4. The overall mean specific activates is shown in figure 3.

</table>

The mean radium equivalent activity of the plants at spring season was 32±2Bq/kg which is higher than the mean values of the plants at summer season 27.2±2.7Bq/kg. The radium equivalent for two groups of silhouette plants is shown in figure 4.

The mean external hazard index, gamma index and alpha index of the plants in spring season were 0.09±0.008, 0.11±0.006, and 0.05±0.006 they were slightly higher than the mean values of the plants at summer season were0.07±0.007, 0.08±0.01, and 0.02±0.004. The block diagram of Hin, Iγ and Iα of two group of silhouette plants is shown in figure 5.
The mean absorbed gamma dose rate of the first group plants $15.3\pm 1\text{nGy/h}$ is higher than the mean absorbed dose rate of the second group $13.2\pm 1.3\text{nGy/h}$, as shown in figure 6.

The mean annual effective dose rate, and the annual gonadal dose equivalent at spring which were $0.07\pm 0.002\text{mSv/y}$, and $0.1\pm 0.006\text{mSv/y}$ are slightly higher than the mean values at summer $0.06\pm 0.1\text{mSv/y}$, $0.09\pm 0.009\text{mSv/y}$. Figure 7 shows the block diagram of the annual effective dose rate and figure 8 annual gonadal dose equivalent plants.
The mean excess lifetime cancer risk at spring 25±0.01 is slightly higher than the mean excess lifetime cancer risk at summer 0.22±0.02. The block diagram of the excess lifetime cancer risk of human of the two season plants is shown in figure 9.
4. Conclusion

A comparison between the radiation hazards of two groups of silhouette plants in two seasons were performed in this study, thus the mean specific activates of spring season plants are higher than the mean specific activates of the summer season plants. Daresenya plant has the highest specific activities, radium equivalent activities, external hazard index, gamma index, alpha index, gamma absorbed dose rate, annual effective dose, annual gonadal dose, and the Excess lifetime cancer risk for spring season plants, while Hedera plant has the lowest for summer season plants results of all these factors are below the recommended limits. This may be due to the, the temperature, moisture and barometric pressure (mbar), as well as the fertilizer used.
